

Interaction matrix

$$R = [r_{ui}] = \begin{bmatrix} \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & r_{ui} & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot \end{bmatrix}$$

m

n

$$R \in \mathbb{R}^{m \times n}$$

m users
 n items

User vectors (rows)

e.g. $r_u = [0, 1, 1, 0, 0, \dots]$

n

Item vectors (columns)

$$r_i = [1, 0, 0, 0, 1, \dots]$$

m

General model

$$\hat{r}_{ui} = f(r_u, r_i | \theta)$$

f - function dependent on parameters θ
which has to be fit to data
so that

$$\text{error} = \sum_u \sum_i d(r_{ui}, \hat{r}_{ui})$$

is minimized

Most often used distance is $d(r_{ui}, \hat{r}_{ui}) = (r_{ui} - \hat{r}_{ui})^2$

Problem

p_u and q_i are very long and sparse (contain mostly zeros)

Solution

Reduce dimensionality of user and item representation

$$p_u \in \mathbb{R}^n \rightarrow p_u \in \mathbb{R}^d$$

$$r_i \in \mathbb{R}^m \rightarrow q_i \in \mathbb{R}^d$$

Reduce dimensionality of ...

$$r_u \in \mathbb{R}^n \rightarrow p_u \in \mathbb{R}^d$$

$$r_i \in \mathbb{R}^m \rightarrow q_i \in \mathbb{R}^d$$

How to do that?

- Dimensionality reduction (PCA, tSNE)
- Matrix factorization

Matrix factorization

Theorem For every matrix $R \in \mathbb{M}_{m \times n}$
there exist matrices $P \in \mathbb{M}_{m \times m}$, $\Sigma \in \mathbb{M}_{m \times n}$, $Q \in \mathbb{M}_{n \times n}$
such that

$$R = P \Sigma Q^T$$

and

- rows of P are orthonormal vectors of $R R^T$
- rows of Q are orthonormal vectors of $R^T R$
- Σ is diagonal and the diagonal consists of square roots of all eigenvalues of R .

A pair of eigenvector v and eigenvalue λ
for a matrix A satisfy the following
equation

$$A v = \lambda v$$

$$\underbrace{m}_{\substack{\uparrow \\ n}} \left\{ \begin{bmatrix} r_{ui} \end{bmatrix} \right\} = \underbrace{m}_{\substack{\uparrow \\ m}} \left\{ \begin{bmatrix} v_1 \\ \vdots \\ v_m \end{bmatrix} \right\} \cdot \underbrace{m}_{\substack{\uparrow \\ n}} \left\{ \begin{bmatrix} e_1 & e_2 & 0 \\ 0 & \ddots & \end{bmatrix} \right\} \cdot \underbrace{n}_{\substack{\uparrow \\ n}} \left\{ \begin{bmatrix} w_1 \\ \vdots \\ w_n \end{bmatrix} \right\}^T$$

v_1, \dots, v_m form orthonormal basis of \mathbb{R}^m

w_1, \dots, w_n form orthonormal basis of \mathbb{R}^n

After changing notation to

$$\begin{bmatrix} \beta_1 \\ \vdots \\ \beta_m \end{bmatrix} = \begin{bmatrix} v_1 \\ \vdots \\ v_m \end{bmatrix} \begin{bmatrix} e_1 & e_2 & 0 \\ 0 & \ddots & \end{bmatrix}$$

and

$$\begin{bmatrix} q_1 \\ \vdots \\ q_n \end{bmatrix} = \begin{bmatrix} w_1 \\ \vdots \\ w_n \end{bmatrix}$$

we have

$$\begin{aligned} \begin{bmatrix} r_{ui} \end{bmatrix} &= \begin{bmatrix} \beta_1 \\ \vdots \\ \beta_m \end{bmatrix} \begin{bmatrix} q_1 \\ \vdots \\ q_n \end{bmatrix}^T \\ &= \begin{bmatrix} \beta_1 q_1 & \beta_1 q_2 & \dots & \beta_1 q_n \\ \beta_2 q_1 & \dots & & \vdots \\ \vdots & & \ddots & \vdots \\ \beta_m q_1 & \dots & \dots & \beta_m q_n \end{bmatrix} \end{aligned}$$

$$\forall_{u,i} \quad r_{ui} = \beta_u q_i$$

Problem

$\beta_u \in \mathbb{R}^n$, $q_i \in \mathbb{R}^n$ where n is large

Solution

Approximate matrix R with only d largest eigenvalues (remove all other rows and columns)

$$R \approx P_d \Sigma_d Q_d^T$$

where

where

$$P_d \in \mathbb{M}_{m \times d}, \quad \Sigma_d \in \mathbb{M}_{d \times d}, \quad Q_d \in \mathbb{M}_{n \times d}$$

Then

$$\forall_{u,i} \quad r_{u,i} \approx p_u \cdot q_i$$

$$\text{and } p_u \in \mathbb{R}^d, \quad q_i \in \mathbb{R}^d$$

Idea for a recommender

Find dense representation vectors $p_u \in \mathbb{R}^d, q_i \in \mathbb{R}^d$ such that

$$MSE = \frac{1}{|R|} \sum_{u,i} (r_{u,i} - \hat{r}_{u,i})^2 = \frac{1}{|R|} \sum_{u,i} (r_{u,i} - p_u \cdot q_i)^2$$

where $|R|$ is the number of interactions used for training.

Then our model is given by

$$\hat{r}_{u,i} = f(r_u, r_i) = p_u \cdot q_i$$

MSE error can be minimized using many methods:

- SGD (Stochastic Gradient Descent)
- ALS (Alternating Least Squares)
- black box optimizers, e.g. Tree Parzen Estimator
